# Concept

Blockstarter is a decentralized application enabling the cryptosphere to crowdfund and crowdcontrol innovative project ideas. The dApp involves three types of stakeholders:

- > Founders: can create projects with budget and milestones
- > Angels: can finance projects and vote on funds release
- > Contributors: can finance project but do not have voting right

Blockstarter 4 / 16

## Workflow - 1

- Founder creates project specifying idea details, total budget requested, milestones (each with description, deadline and percentage of fund release)
- Anyone can fund to the project, contributions above 1% of the total requested budget grant Angel rank.
- Once the requested budget is achieved, the project starts. Founder is supposed to communicate through an external service (website, social networks, etc) the evolution of the project to the community. Contributions can still take place.

Blockstarter 5 / 16

## Workflow - 2

- When a milestone's deadline is reached, the founder can request the associated funds
- > Contributors can request their funds back any time
- Angels can decide any time to request the project to halt (resume) if they are dissatisfied (reassured) with the project development. Delays induced by haltings are added to the milestones original deadline.
- > Upon the final milestone completion, remaining funds are all transferred to the founder.

## Implementation - Structure

Hierarchy of three classes:

> ProjectBase: core components of a project

> ProjectWithMilestones: milestone logic

> ProjectWithAngels: angel rank voting logic

And an additional library for the milestone struct and milestone array validation: ProjectUtils

Blockstarter 8 / 16

# Implementation - ProjectBase

## Members

#### name type founder address string name description string budget uint totalReceived uint bool started completed bool received $addr \Rightarrow uint$

### **Events**

- ProjectStarted
- ProjectCompleted

### **Modifiers**

- isFounder
- hasFunds
- projectRunning

Blockstarter 9 / 16

## Implementation - Milestones

```
struct Milestone {
  bool completed;
  string description;
  uint deadline;
  uint percentageOfBudget;
}
```

- > inherits from project base
- > each project has array of milestones
- > not all funds released at once
- individual deadlines
- individual payouts

Blockstarter 10 / 16

# Implementation - ProjectWithAngels

- > inherits from project with milestones
- > users that contribute a certain amount become angels
- angels can request to halt / resume the project
- > when the project is halted, no funds can be released by the founder
- > when a project is halted, the open milestones are delayed
- Emits events when new angel is born or project is halted / resumed

## Project creation

The main contract provides means to create a new project:

name	type	example	
name	string	need	
description	string	gib me monies	
requestedBudget	uint	32*10 <sup>18</sup>	
founder	address	0×1337C0D3	
descriptions	string[]	["phase 1", "phase 2"]	
deadlines	uint[]	[1607989310 ,1607999310]	
percentages	uint []	[29, 71]
